

Project Context

An interface that helps church organizers and youth leaders structure and present event information so attendees know what to expect and increase their confidence. The primary tasks being evaluated are where the user are struggling or lack confidence in their actions.

Heuristic Evaluation

Hypothesis: If navigation labels and system feedback are more consistent across screens, then users will make fewer mistakes and feel more confident in their actions, because the interface will better follow usability principles and visibility of system status.

Issues:

- Weak system feedback
- Error prevent is weak

Conclusion: The hypothesis was supported. However, these issues impact clarity, confidence, and efficiency.

Cognitive Walkthrough

Hypothesis: If the primary next step is clearly highlighted and the flow is broken into smaller steps, then first-time users will complete the task with less hesitation because the interface will better guide decision-making will be proving user actions are acceptable.

Issues:

- Navigation is straightforward
- Could use more navigation in third flow

Conclusion: Hypothesis is supported. User can clearly see where to navigate and what to press. User action is acceptable and improves confidence and efficiency.

First Click Test

Hypothesis: If the primary action button is visually prominent and placed in a predictable location, then users will click the correct first step more often because the interface will align with common user patterns.

Issues:

- First click is visually present throughout all flows

Conclusion: The hypothesis is supported. The first click throughout all flows are visually present and specific.

Design Improvements

1. Clear Successful Feedback Message
Stronger system feedback when saving information.

Why?

Gives users confidence their actions are acceptable

2. Clear error prevention
Provide stronger error feedback for users

Why?

Gives users confidence to complete information without forgetting or missing important steps.

3. First Click Navigation (Third Flow)

Provide navigation to the 'Exit Preview Button' in the third flow

Why?

Allows for smoother flow and gives users access to navigating when pressing a button.

Cross-Method Synthesis

The patterns that appeared across methods was first click. The users' first option to navigate was always visible and presentable. It made the navigation smoother and gave the user confidence in their navigation of the prototype. The issues that were most important were weak error and success feedback. Another was a navigation button that did not lead to anywhere after being pressed in the third flow. The pattern helped especially in my last flow when it was mentioned to me by a user that the 'Exit Preview Mode' button did not lead anywhere. I then added a navigation for button. In addition, it helped me with my main issues of a weak success and error messages.

Reflection

When running the tests, the issues found were not visual designs, but more so the technical response to user actions. This gave the users less confidence in their actions and made the flows less efficient. The thing that changed most significantly in my design is the details of each flow and the navigations the users can use. This gives my design a much more in-depth technical structure while giving the user easier navigation in the prototype. The improvement that changed most significantly in my design was a success message in my second flow. It helps smooth out the prototype while giving the user confidence their action was accepted. The one thing I would test next would be if linking the payment methods to the first flow in the 'Parent Info' section.
